## Introduction

The effect of dormancy is often ignored when it comes to investigating speciation and extinction rates. However, dormancy may be impacting population sizes and growth rates in important ways that influence the evolution of species and the diversity we see in phylogenies. The interplay of dormancy in response to competition raises the question: how much does dormancy effect speciation and extinction in the presence or absence of competition? According to Lennon et al. (2021), species that engage in dormancy may have a lower extinction rate because individuals are able to escape into the "seed bank" during times of high competition. On the other hand, escaping into the "seed bank" with dormancy reduces the effective population size of reproductive individuals, thereby limiting the population growth rate. If dormancy is considered an evolved trait, how does it effect speciation and extinction rates in the presence or absence of competition?

I will use MuSSE (FitzJohn 2012) to test for optimal parameters for speciation and extinction rates in lineages that are or are not capable of dormancy and have or have no competition present. In addition, the rate of escape into the "seed bank" will be optimized for the phylogeny presented. Although this example only uses example data, the concept could be applied to a phylogeny with varying life history strategies and levels of competition. After optimizing MuSSE, it would be wise to consider hidden traits that may be influencing the speciation and extinction rates using HiSSE (Beaulieu & O'Meara 2016).

## Import data

I will be using phylogeny and trait data from homework 8 to make and test the model. I want to have all possible trait combinations, so everything in the *Hylobates* genus has 1 for T1 (warning: this is now made-up data!).

```
require("corHMM")
require(phytools)
data(primates)
primates$trait[which(grepl("Hylobates", primates$trait[,1])),2] <- 1</pre>
```

Look at the trait data to see all possible combinations.

```
head(primates$trait, 20)
```

```

## Make the tree bifurcating

MuSSE complained that the tree wasn't bifurcating, use multi2di to make the tree bifurcating.

Make a BiSSE function using make bisse. Use this function to test all the different hypotheses of speciation, extinction, and transition rates.

bis() is now a function. Needs parameters lambda0, lambda1, mu0, mu1, q01, q10.

```
SpN = lambda0 = \# speciation rate, no dormancy SpD = lambda1 = \# speciation rate, dormancy (/p) ExN = mu0 = \# extinction rate, no dormancy ExD = mu1 = \# extinction rate, dormancy (/p) TrN = q01 = \# transition rate, no -> dormancy TrD = q10 = \# transition rate, dormancy -> no p = \# escape rate
```

The results are in log-likelihood, so use  $\exp()$  to make comparisons easier. The most positive likelihood is best. For example:  $\exp(\operatorname{bis}(\operatorname{c}(1,2,3,1,2,3)))$ 

```
startparambisse <- starting.point.bisse(tree = primates$tree)</pre>
```

 $lambda0\ lambda1\ mu0\ mu1\ q01\ q10\ 0.06882283\ 0.06882283\ 0.000000000\ 0.00000000\ 0.01376457\ 0.01376457$ 

```
bis_fit <- find.mle(bis, startparambisse)

Need to first make a trait that has 0-3 representing 0A, 1A, 0B, 1B.

Use MCMC to find the distribution of likelihoods. Use the optimized parameters to hopefully start in a better place. Start by making the output file.

# file.create("/Users/hollybrabazon/Documents/PhD\_UTK\_EPP/Course\_work/EEB587\_PhylogeneticMethods/Phylog

Then use mcmc().

Make a function that creates all 20 parameters as random numbers based on dormancy rules.

```
generator <- function(p, musse_fn) {</pre>
   lambda1 \leftarrow runif(1, min = 0, max = .1)

Run the above function multiple times.

```
test1 <- generator(p = 5, musse_fn = musse_fn)
# rep(p, repetitions)
res <- map_dfr(.x = rep(seq(from = 1, to = 10, by = 0.2), 10), .f = ~generator(p = .x, musse_fn = muss
```

Plot p (escape rate) vs. log.likelihood.
